Why Nano?

Condensation Particle Counters (CPCs)

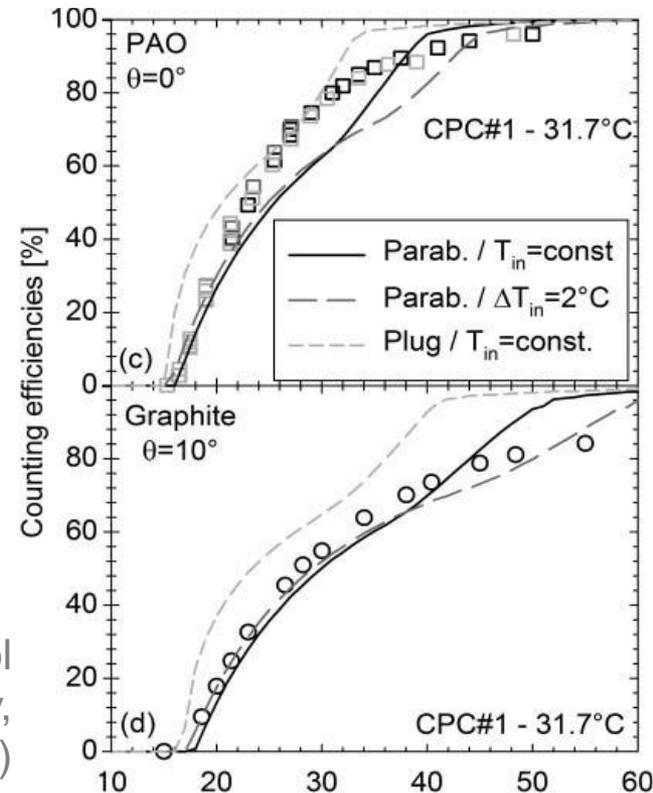

Droplets nucleate and grow in a CPC on nanoparticles

... with fast dynamics, coupling of heat and mass transfer, **droplets are polydisperse**, and a size change typically 3 orders of magnitude ...

- **Where** do these phenomena take place?
- What is the final **droplet size distribution**?
- How can we **troubleshoot CPCs**?

Droplets nucleate and grow in a CPC on nanoparticles

- **What** is the challenge?

poly-
(alpha)-
olefin
(PAO)

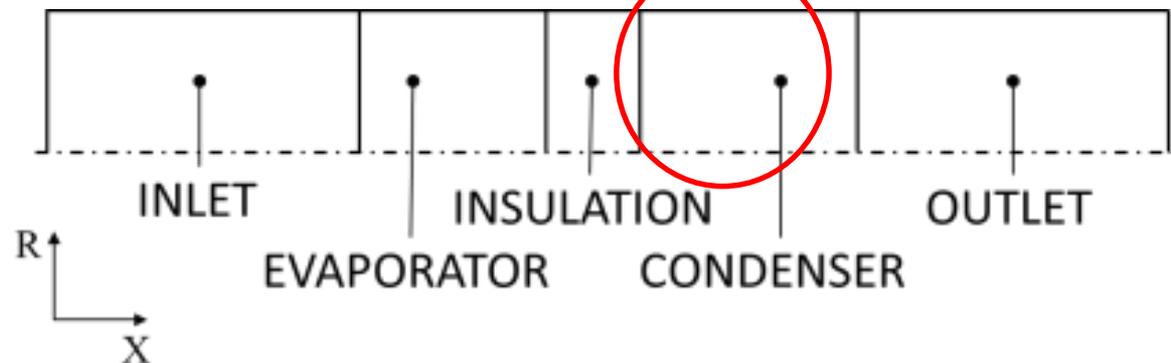

Mamakos et al., Aerosol
Science and Technology,
47:11-21 (2013)

The Models

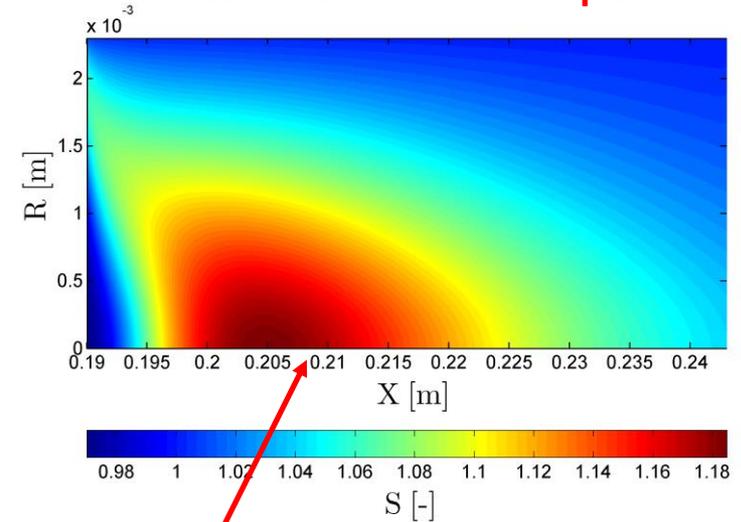

Multiphase Flow inside the CPC

- **continuous phase** (e.g., n-Butanol vapor in air)
 - modeled with the **cpcFoamCompressible** solver implemented in OpenFOAM
 - all effects **relevant for CPCs** considered (thermodiffusion, heat of evaporation / condensation, etc.)
- **disperse phase**
 - **qmomCloud** library
 - solves the population balance equation for the droplets using a **QMOM approach** (univariate in droplet diameter)

(a) Evaporator-Condenser system in a CPC

(b) saturation ratio profile – solution for the continuous phase

Moment Transport Equations

- Moments approximate the NDF
- Moments have a physical meaning:
 - m_0 number concentration [m^{-3}]
 - m_1 total droplet size p. vol. [m^{-2}]
 - $L_{32}=m_3/m_2$... Sauter mean diameter [m]
- If \mathcal{R} term unclosed, reconstruct NDF with QMOM (set of N nodes and N weights)
- \mathcal{R} terms determined by physical models

$$\frac{\partial m_0}{\partial t} + \frac{\partial}{\partial x_i} (u_i m_0) = \mathcal{R}_0$$

$$\frac{\partial m_1}{\partial t} + \frac{\partial}{\partial x_i} (u_i m_1) = \mathcal{R}_1$$

⋮

$$\frac{\partial m_k}{\partial t} + \frac{\partial}{\partial x_i} (u_i m_k) = \mathcal{R}_k$$

⋮

$$\frac{\partial m_{2N-1}}{\partial t} + \frac{\partial}{\partial x_i} (u_i m_{2N-1}) = \mathcal{R}_{2N-1}$$

Moment Transport Equations (Example)

$$\frac{\partial m_k}{\partial t} + \underbrace{\frac{\partial}{\partial x_i} (u_i m_k)}_{\text{advection}} = \underbrace{\left[2 \frac{\rho_f}{\rho_l} D_v Sh \ln(1 + B_m) \right] k m_{k-2}}_{\text{growth}} + \underbrace{J_{het} (d_{d,init}/2)^k}_{\text{nucleation}}$$

Unclosed for $k = 0$
and $k = 1$

$k = 0, \dots, 2N - 1$

Solution for the disperse phase approximated by time evolution of first $2N$ moments ($m_0, m_1, \dots, m_{2N-1}$)

Quadrature Method of Moments

Approach

- moments are approximated by N weights w_α and N nodes ξ_α
- weights and nodes are calculated with the first $2N$ moments (e.g., PD algorithm)

$$m_k = \int_{\Omega_\xi} \xi^k n d\xi \approx N_p \sum_{\alpha=1}^N \xi_\alpha^k w_\alpha$$

Result

- the first $2N$ moments are reproduced exactly
- unknown moments in the **source terms of the moment transport equations** can be computed to close the system of equations!!

$$\frac{\partial m_k}{\partial t} + \frac{\partial}{\partial x_i} (u_i m_k) = \left[2 \frac{\rho_f}{\rho_l} D_v Sh \ln(1 + B_m) \right] k \underbrace{N_p \sum_{\alpha=1}^N \xi_\alpha^{k-2} w_\alpha}_{m_{k-2}} + J_{het} (d_{d,init}/2)^k$$

Growth Models

0) The Basics

$$\dot{\xi} = 2 \frac{\dot{m}_{cond}}{\rho_l \xi^2 \pi}$$

Mass
concentration

$$\dot{m}_{cond} = Sh \pi D_v \xi \Delta c$$

Key scaling of the growth
rate in the case of mass
transfer limitation

$$\dot{\xi} = 2 \frac{Sh D_v}{\xi} \frac{1}{\rho_l} \Delta c$$

$$\dot{\xi} \propto 1 / \xi$$

...inserted into the moment
evolution equations yields...

$$\frac{Dm_k}{Dt} = \left[\dot{\xi} \xi \right] k m_{k-2}$$

...in case we assume that:

$$\dot{\xi} \xi \neq f(\xi)$$

Growth Models

1) Simple Continuum-Regime Closure (thermal equilibrium, dilute vapor, large droplets)

$$\dot{\xi} = 2 \frac{Sh D_v}{\xi} \frac{1}{\rho_l} \frac{1}{R_{g,vap}} \left(\frac{p_{vap}}{T} - \frac{p_{vap}^{sat}(T_d)}{T_d} \right)$$

2) Classical Closure (Abramzon & Sirignano, 1989; thermal equilibrium, large droplets)

$$\dot{\xi} = 2 \frac{Sh D_v}{\xi} \frac{\bar{\rho}_{gas}}{\rho_l} \ln(1 - B_m)$$

← considers Stefan flow

$$B_m = \frac{y_{vap}^{sat} - y_{vap}}{1 - y_{vap}^{sat}}$$

Growth Models

3) Free-Molecule-to-Continuum-Regime Closure (Fuchs and Sutugin, 1970; Ahn and Liu, 1990)

$$\dot{\xi} \xi \neq f(\xi)$$

... only approximate, because of **correction factors!**

$$\dot{\xi} = 2 \frac{Sh D_v}{\xi} \frac{1}{\rho_l} \frac{1}{R_{g,vap}} \left(\frac{p_{vap}}{T} - \frac{K_{Kelvin} p_{vap}^{sat}(T_d)}{T_d} \right) \phi_F(\bar{\xi})$$

$$K_{Kelvin} = \exp\left(\frac{4 \sigma MW_{vap}}{\rho_l R_{g,vap} T_d \bar{\xi}}\right)$$

$$\phi_{F,i}(\bar{\xi}) = \frac{1 + Kn_i}{1 + 1.7104 Kn_i + 4/3 Kn_i^2}$$

$$Kn_i = 2 \lambda_i / \bar{\xi}$$

$$(T_d - T) \lambda_{air} \frac{Nu}{\bar{\xi}} = D_v \frac{Sh}{\bar{\xi}} \Delta h_{evap} \frac{1}{R_{g,vap}} \left(\frac{p_{vap}}{T} - \frac{K_{Kelvin} p_{vap}^{sat}(T_d)}{T_d} \right) \frac{\phi_{F,vap}(\bar{\xi})}{\phi_{F,g}(\bar{\xi})}$$

Expensive: **iterations** are required to determine T_d .

Nucleation Model

1) Standard Heterogeneous Nucleation Model

$$J_{het} = J_{het}^0 \exp\left(-\frac{\Delta G_{het}^*}{k_B T}\right)$$

A larger number

$$J_{het}^0 = d_p^2 \pi 10^{29}$$

Particle Geometry
& Contact Angle

$$\Delta G_{het}^* = f_g \Delta G_{hom}^*$$

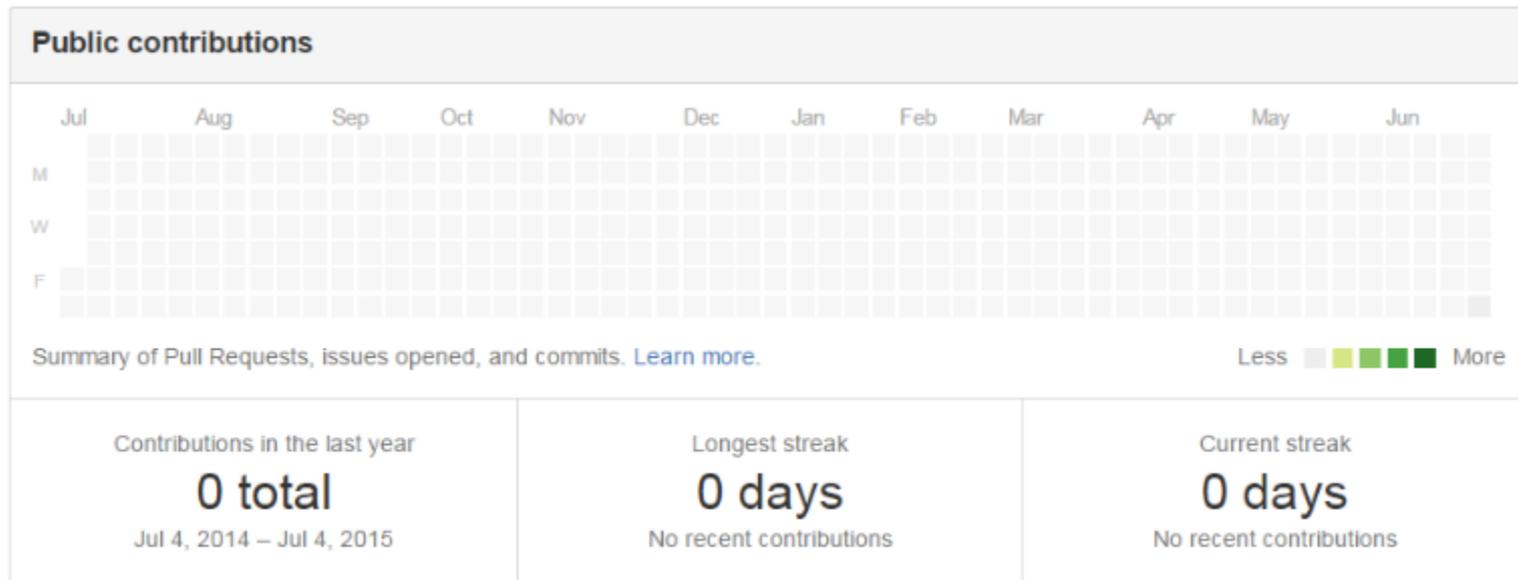

$$\Delta G_{hom}^* = \frac{4}{3} \pi (r^*)^2 \sigma$$

$$r^* = \frac{2\sigma}{\rho_l R_{g,vap} T \ln(S)}$$

The Software

Unfortunately, there is no publicly-available (x)MOM implementation in OpenFOAM!

<https://github.com/OpenQBMM>

So, let's start from scratch:

- **cpcFoamCompressible** as new solver
- **qmomCloud** for modeling **droplets**

cpcofm
